

Feature Request 01: Onboarding and Authentication

Submission Date: Friday, 7th August 2026

Pre-requisites

Before starting this task, make sure you have:

- Watched https://www.youtube.com/watch?v=Qsq-Sj_rojU and formed a view on what separates an onboarding flow that holds someone's attention from one they abandon. Not everything in it applies to this product. Bring judgement, not a checklist.
- A working understanding of the Git workflow: branching, pull requests, review, and merge. [\(6000\) Git + GitHub Branches, Forks, and Pull Requests - YouTube](#)

Description

What is an Onboarding Flow?

An onboarding flow is the sequence a new user moves through between arriving at a product and reaching the point where it becomes useful to them. It covers what the product explains about itself, what it asks the user for, and in what order. Authentication is one step inside that sequence, not the entrance to it.

Why Design the Onboarding Flow?

A well-designed onboarding flow helps teams:

- Establish what the product is before asking the user to commit anything.
- Decide what information is genuinely required and what can be skipped.
- Reduce abandonment at the point of highest drop-off risk.
- Separate the account and billing surfaces from the product surface.
- Set the structural and copy patterns that every later feature will inherit.

Task

Design and build the onboarding and authentication flow for the owner of a memoir i.e. the family member who creates it, pays for it, and invites everyone else.

The flow must follow this order:

Onboarding (collect information) → Authentication

By the end of it, the information should exist in the database while building the memoir is out of scope for this feature request. The owner should have an account by the end of the process.

Within that order, the sequence is yours to design. How many screens, what you ask for, what is optional, and how the flow is paced are your decisions.

The onboarding portion should be engaging. A plain form will technically satisfy this task and will not pass review. Find something more interesting to do with the information you are collecting than putting it in input fields. Show creativity here, this is the part of the task being judged on design thinking rather than correctness.

In scope: the owner's path only, from first arrival through to the account creation.

Out of scope: the contributor's experience of opening that link, memory capture, transcription, chapter organization, publishing, and comments.

Deliverables

1. A short flow specification of the screens, what each is for, and what is required versus optional.
2. Working onboarding, authentication for the memoir owner.
3. A repository with a real commit history. See below for details.

All work is delivered through GitHub. One team member creates the repository and adds the rest of the team to it. Everyone else clones it. Every work item is built on its own branch and submitted as a pull request i.e. no direct commits to the main branch. Pull requests must describe what was built and why, and must be reviewed before being merged. How you assign reviewers within the team is up to you.

The commit history is part of the deliverable. A repository whose work arrives in one commit at the end has not met this requirement, regardless of what it contains.

Work Allocation

Group members claim work rather than being assigned it. Service and data work is claimed by AI Backend students; screens and client-side work by Full-Stack students.
